

Incident report analysis

Instructions

As you continue through this course, you may use this template to record your findings after completing an activity or to take notes on what you've learned about a specific tool or concept. You can also use this chart as a way to practice applying the NIST framework to different situations you encounter.

Summary	The organization's network stopped responding due to a flood of ICMP packets. The team blocked the incoming packets and stopped all non critical network services to restore the critical network services. After investigating, the team found a malicious actor had flooded the network through an unconfigured firewall and overwhelmed the network with a DoS attack.
Identify	The attacker flooded the network with an ICMP attack, affecting the entire network. This required the critical network resources to be restored to a functioning state.
Protect	A new firewall rule was implemented to limit the rate of any incoming ICMP packets. A IDS/IPS system was also implemented to filter out some ICMP traffic based on suspicious characteristics.
Detect	A source IP address verification was configured to the firewall to check for any spoofed ip addresses on the incoming ICMP packets and a network monitoring software was used to detect abnormal traffic patterns
Respond	In the future, the security team will minimize risk of any attacks by segmenting affected parts of the network. They will analyze the logs to check for any abnormalities within the network and report any findings and issues to

	management and the appropriate authorities, along with communicating with the rest of the staff and team if necessary.
Recover	To properly recover, any non major network services had to be brought down to restore the critical network services to a functioning state. Any future ICMP attacks can be blocked at the firewall until the ICMP packet flood times out. AT that point, the non critical services can be restored properly.
